System workflow | Patient care

Read from top to bottom. Prescriptions, laboratory work and follow-up tasks are optional branches of a visit.

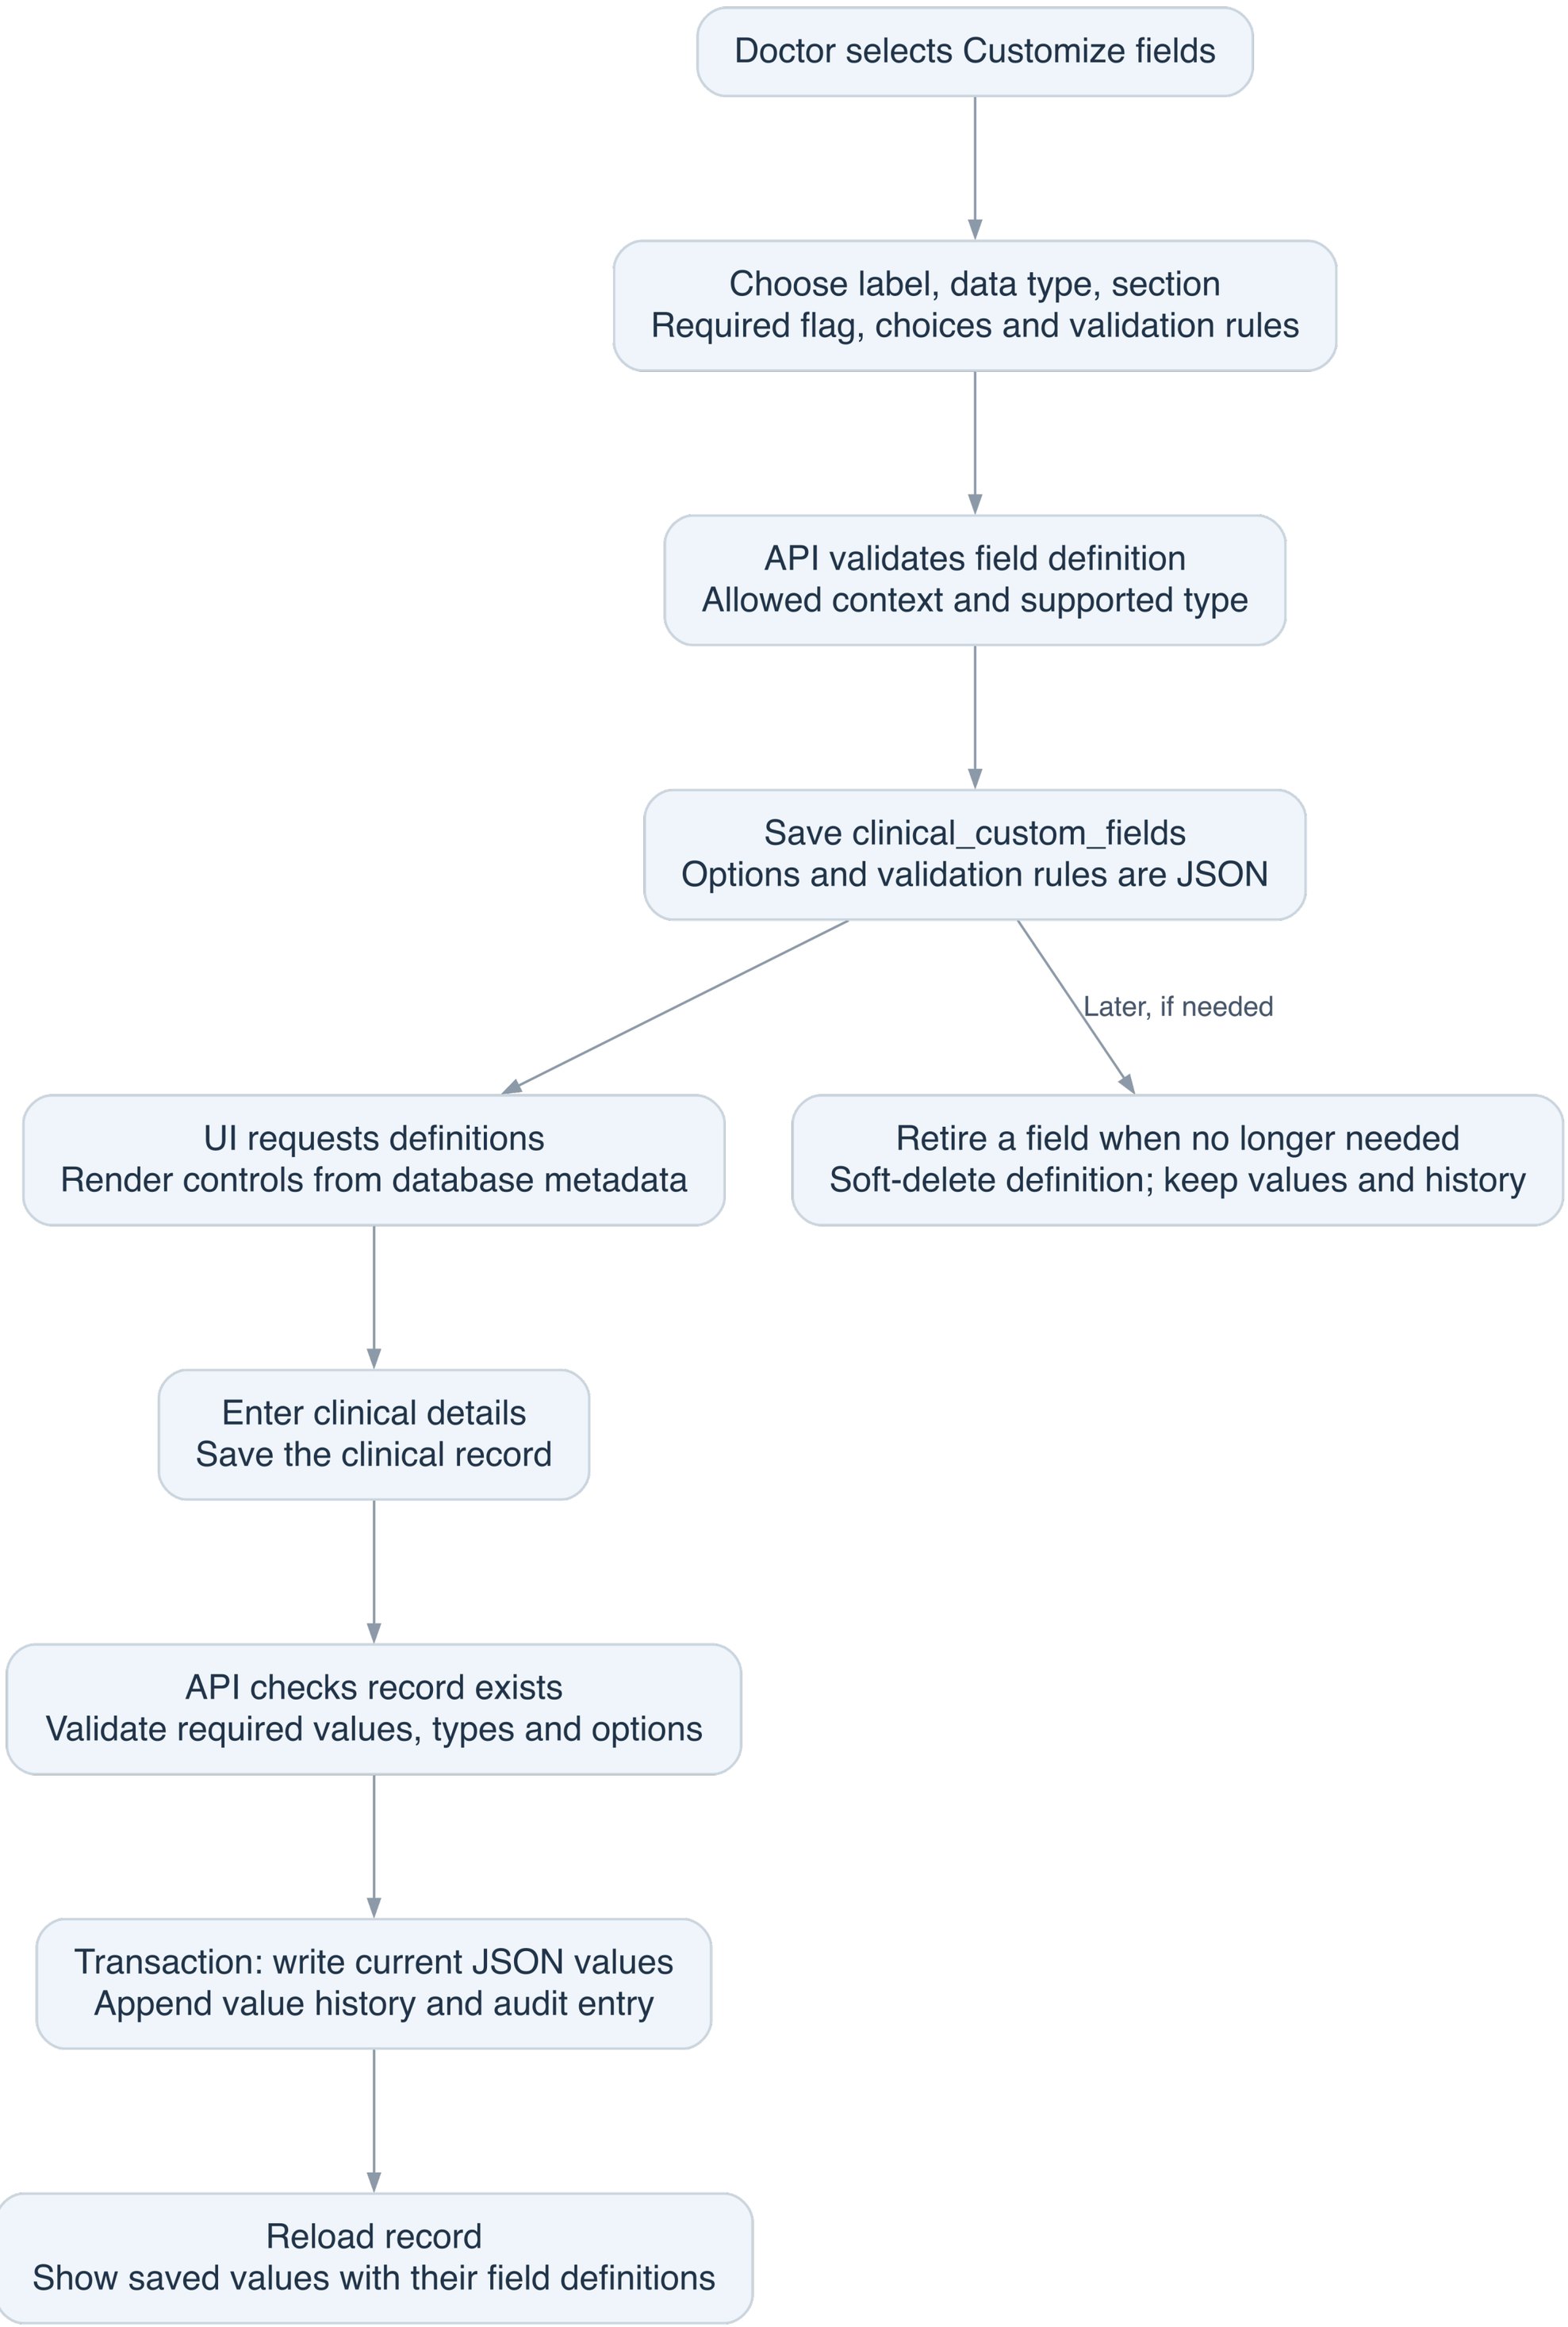

The repeat-visit loop is a staff workflow; the system does not automatically link a completed follow-up to the later visit.

Appointments and insurance records exist in the database. The current UI does not provide a complete appointment-booking or insurance-editing workflow.

System workflow | Customize any clinical form

The same dynamic-field component serves patients, visits, prescriptions, labs, allergies, immunizations and follow-ups.

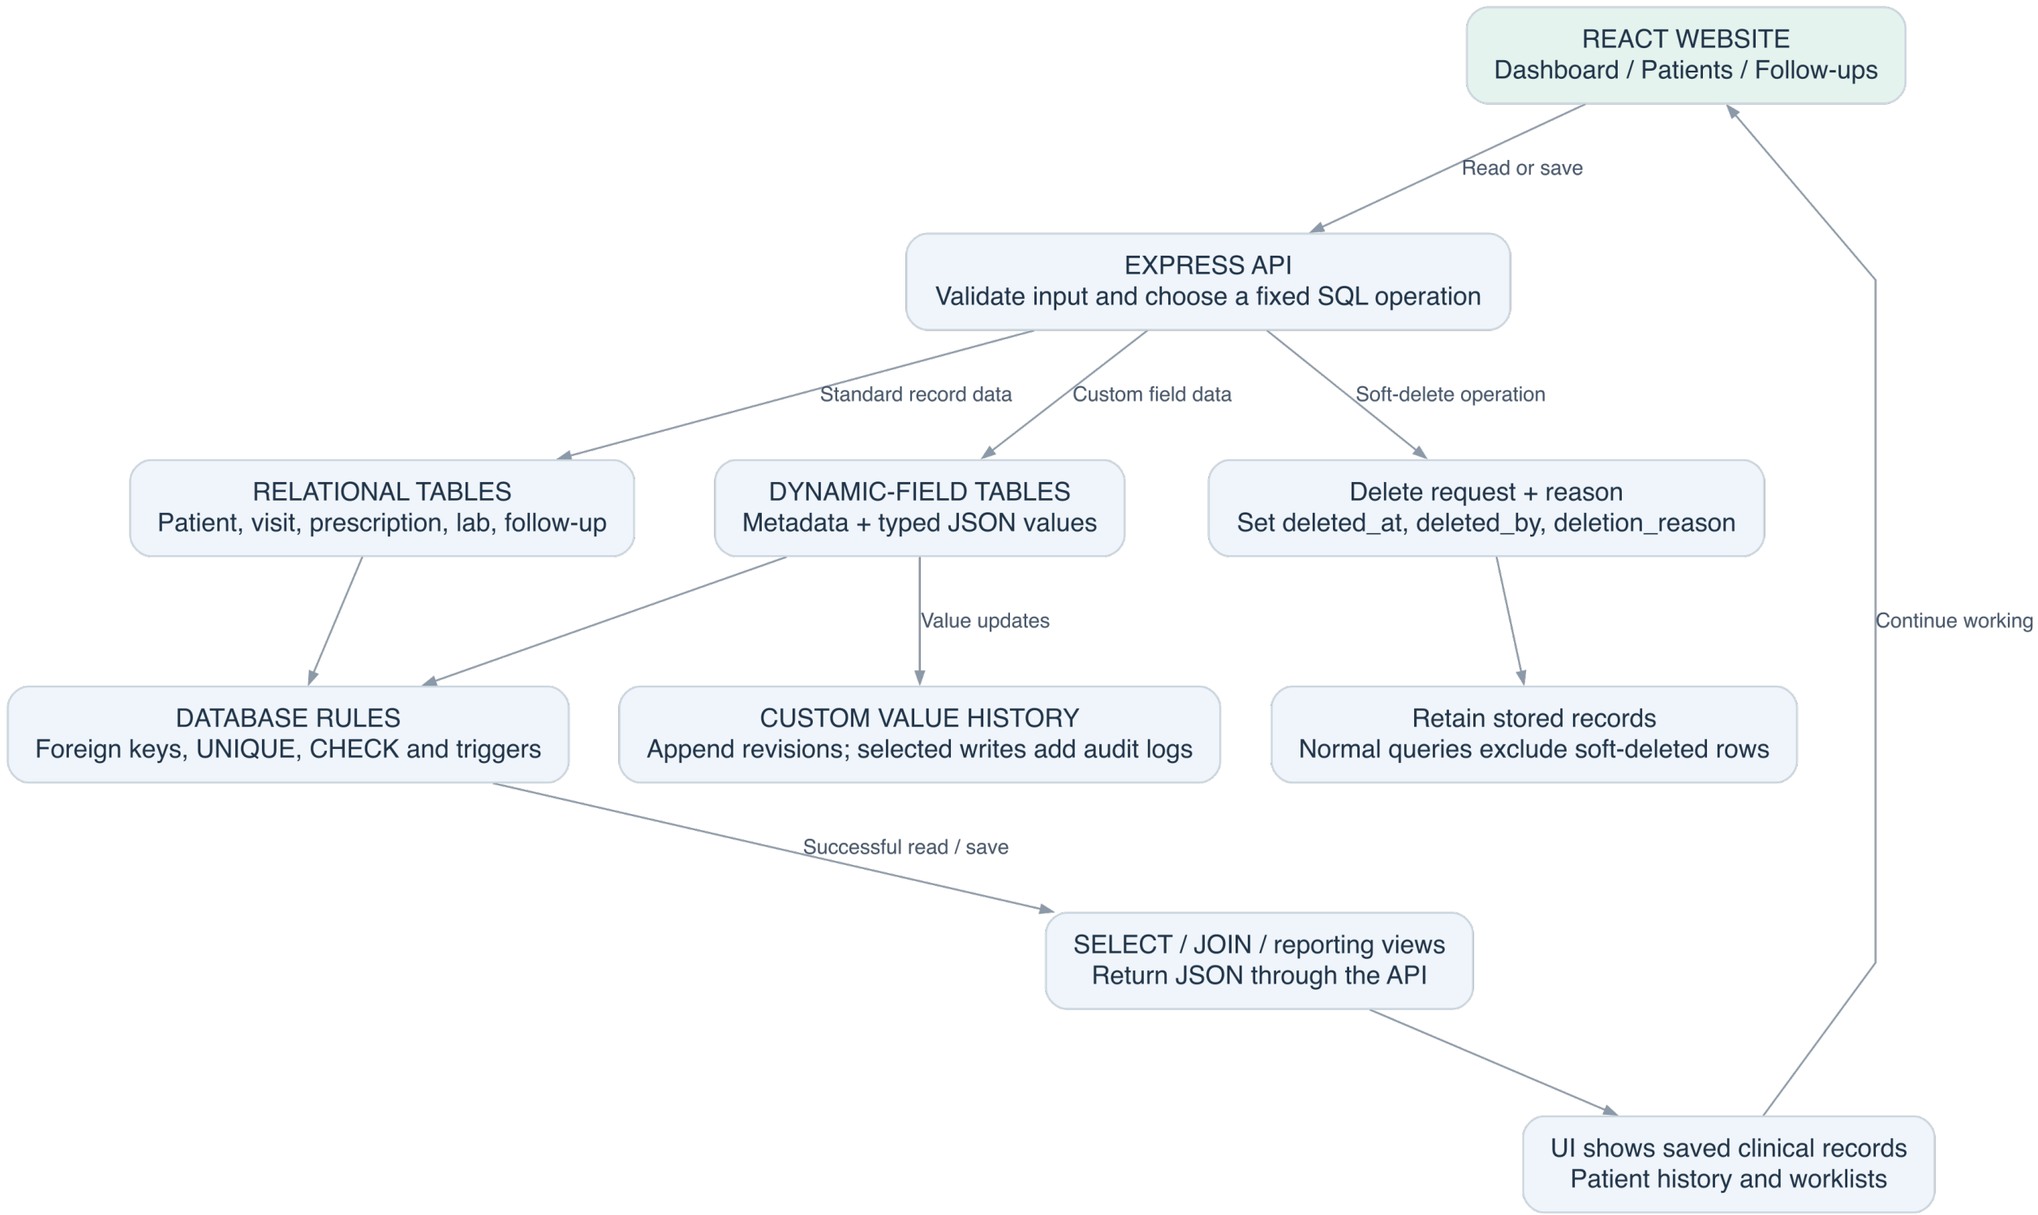

No database column is added when the doctor adds a custom field. A metadata row defines the field, and a value row stores each answer.

The base clinical record and its custom values are saved through separate API calls. The custom-value batch itself uses a transaction.

Retired definitions and their values remain in the database; the active-field UI filters out retired definitions.

System workflow | Read, write and preserve data

The website uses React, an Express API and MySQL. The diagram shows implemented data paths.

Audit and history links use restrictive retention relationships. Existing data is not physically removed by the clinical soft-delete APIs.

The current prototype uses seeded user_id = 1 for audit actions. Role tables do not yet provide an actual login or enforced authorization flow.
