JSON explained | What the website actually saves

The current website stores one typed JSON value for each field and record. It does not put every answer into one response object.

clinical_custom_fields | metadata

custom_field_id	context_type	field_key	field_type
501	follow_up	pain_score	number
502	follow_up	review_needed	boolean
503	follow_up	symptom_note	text

FK custom_field_id + API validation

clinical_custom_field_values | typed JSON

follow_up_id	custom_field_id	value_json
42	501	7 (JSON number)
42	502	true (JSON boolean)
42	503	"Itching improved" (JSON string)

Save revised values with version history

clinical_custom_field_value_history | revisions

custom_value_id	version	value_json
9001	1	6
9001	2	7

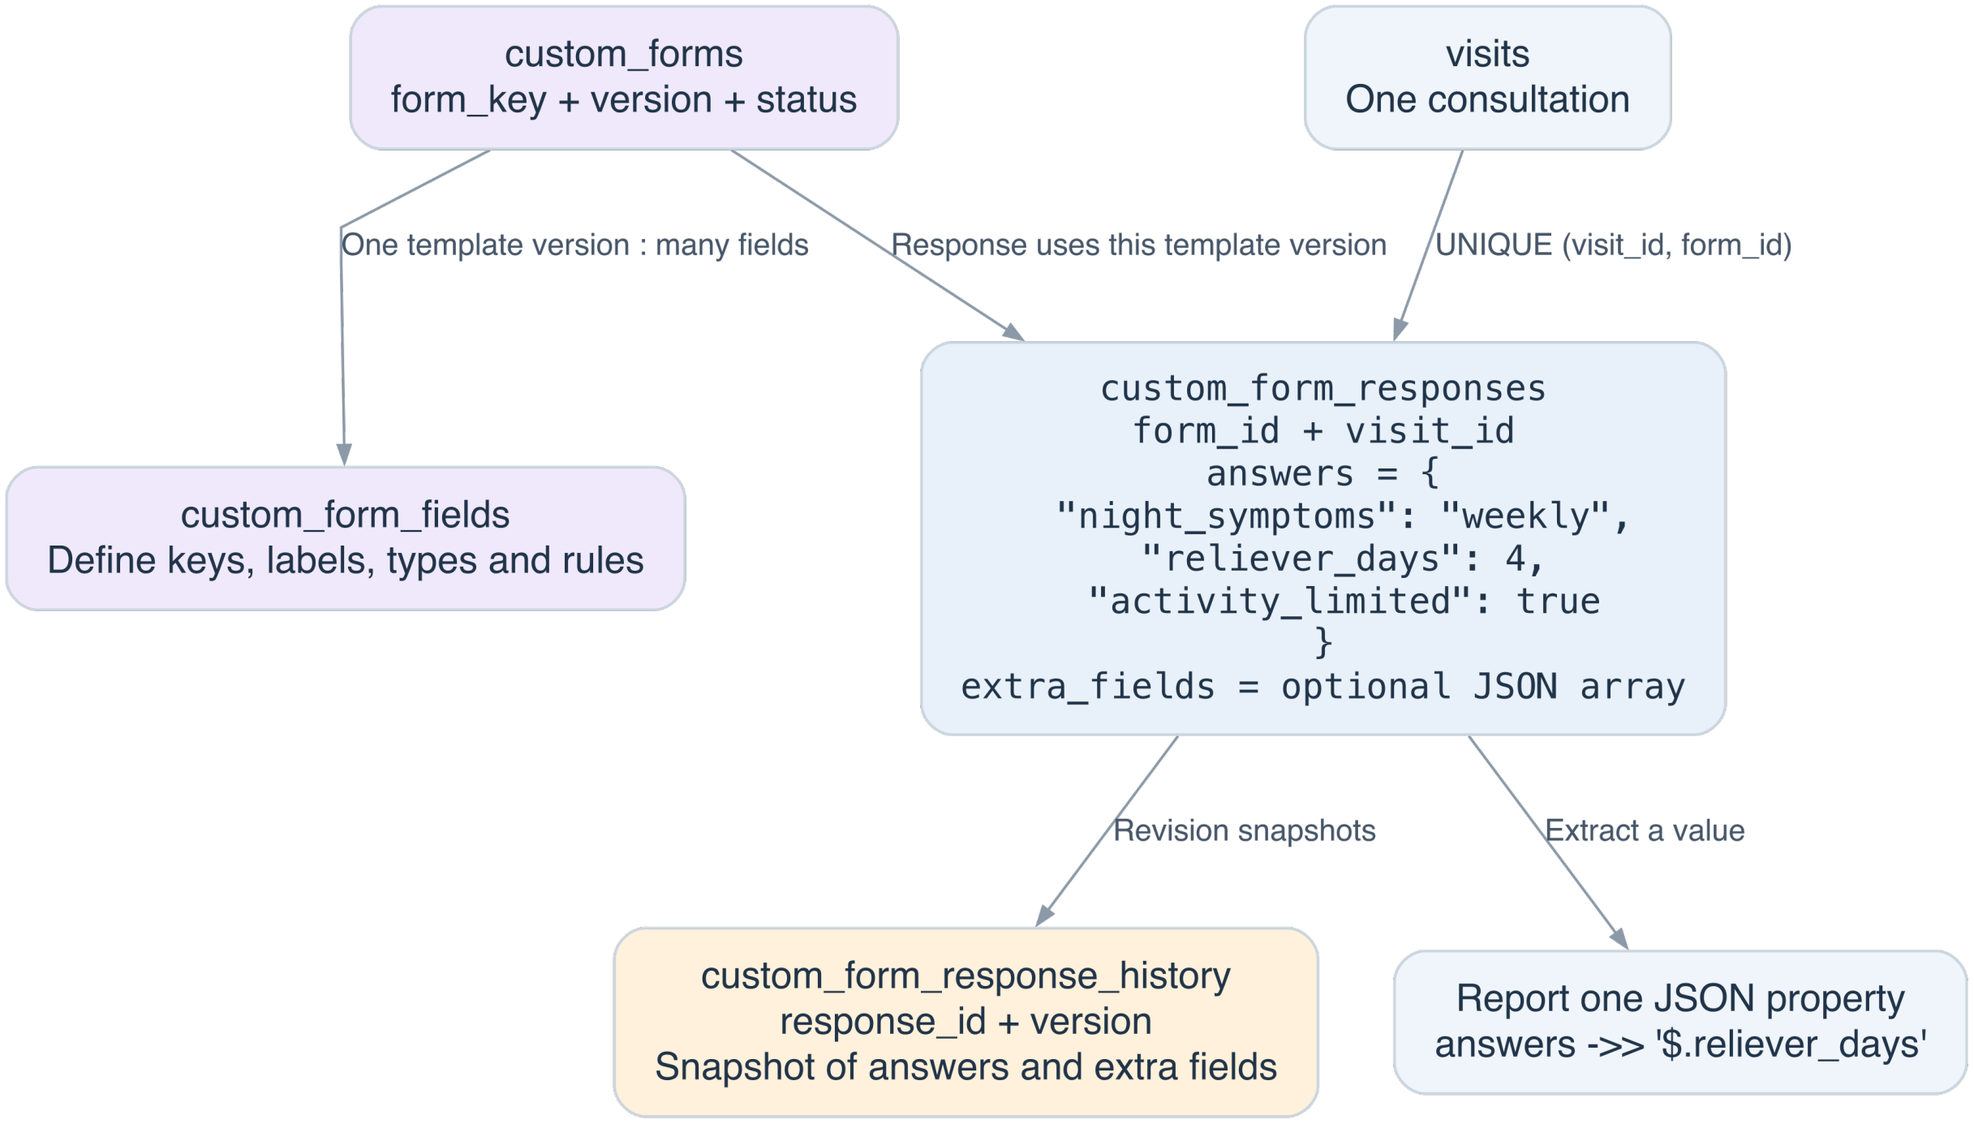

JSON supports strings, numbers, booleans, arrays, objects and null. Dropdown/checkbox options and validation rules also use JSON.

Exactly one owner column is populated: patient_id, visit_id, prescription_id, lab_order_id, allergy_id, immunization_id or follow_up_id.

JSON preserves value types. The API enforces field-specific rules; foreign keys and triggers enforce relationships. Examples above are illustrative, not seeded records.

JSON explained | Whole-response document model

These questionnaire tables remain in the database for evaluation. Their separate builder page and API have been removed.

Here, all questionnaire answers are keys inside one JSON object. A response is linked to one visit and one template version.

JSON_TYPE checks the document shape; it does not enforce each field definition or make a template immutable. Those rules need a controlled write path.

Compare: active website = one JSON value per field; questionnaire model = one JSON object per form response. Both retain relational foreign keys.
